www.bestworstmethod.com
MCDM problem

- **Decision-making** is generally defined as the cognitive process of selecting an alternative from a set of alternatives.

- A **multi-criteria decision-making (MCDM)** problem is a problem where a decision-maker has to find the best alternative from a set of alternatives **considering a set of criteria.**
MCDM problem (example 1)

A shipper has to select the best port among a set of four ports: Le Havre (France); Antwerp (Belgium); Rotterdam (Netherlands); Hamburg (Germany)

Considering the criteria:

- port efficiency
- port infrastructure
- location
- port charges
- interconnectivity
MCDM problem (example 2)

A manufacturer has to select the best location for its central warehouse from a set of three alternative locations: Utrecht; Arnhem; Dordrecht

Considering the criteria:

- proximity to customers
- proximity to suppliers
- investment costs
- expansion possibility
- road connection
- rail connection
- water connection
MCDM problem (example 3)

I want to buy a car from the following set:

Considering the criteria:

- price
- quality
- comfort
- safety
- style
## MCDM problem (formulation)

A discrete MCDM problem is generally shown as a matrix as follows:

\[
P = \begin{pmatrix}
    c_1 & c_2 & \cdots & c_n \\
    a_1 & \begin{pmatrix} p_{11} & p_{12} & \cdots & p_{1n} \end{pmatrix} \\
    a_2 & \begin{pmatrix} p_{21} & p_{22} & \cdots & p_{2n} \end{pmatrix} \\
    \vdots & \vdots & \ddots & \vdots \\
    a_m & \begin{pmatrix} p_{m1} & p_{m2} & \cdots & p_{mn} \end{pmatrix}
\end{pmatrix}
\]

where

\( \{a_1, a_2, \cdots, a_m\} \) is a set of feasible alternatives (actions, stimuli),

\( \{c_1, c_2, \cdots, c_n\} \) is a set of decision-making criteria, and

\( p_{ij} \) is the score of alternative \( i \) with respect to criterion \( j \).
MCDM problem (goal)

The goal is to select* the best (e.g. most desirable, most important) alternative (an alternative with the best overall value $V_i$)

(*other goals: rank, sort)

$$V_i = \sum_{j=1}^{n} w_j p_{ij}$$

$$w_j \geq 0, \sum w_j = 1$$

The scores $p_{ij}$ are collected from available data sources (if they are objective and available, e.g. price), or measured using qualitative approaches (e.g. Likert scale), or calculated similar to the weights of the criteria (if they are subjective, e.g. quality) and normalized using a normalization formula.
BWM (pairwise comparison)

BWM uses pairwise comparison* to find the weights \((w_j)\) of the criteria.

- Pairwise comparison \(a_{ij}\) shows how much the decision-maker prefers criterion \(i\) over criterion \(j\).
- To show such preference, we may use Likert scales (e.g. very low ... very high) with a corresponding numerical scale like:
  - \(0.1, 0.2, \ldots, 1\) (0.1: equally important, ..., 1: \(i\) is extremely more important than \(j\)).
  - \(1, 2, \ldots, 100\) (1: equally important, ..., 100: \(i\) is extremely more important than \(j\)).
  - \(1, \ldots, 9\) (1: equally important, ..., 9: \(i\) is extremely more important than \(j\)).

[www.bestworstmethod.com](http://www.bestworstmethod.com)
Steps of BWM: Step 1

- **Determine a set of decision criteria.**

In this step, the decision-maker considers the criteria \( \{c_1, c_2, \ldots, c_n\} \) that should be used to arrive at a decision. For instance, in the case of buying a car, the decision criteria can be:

\[
\{\text{quality (} c_1 \text{), price (} c_2 \text{), comfort (} c_3 \text{), safety (} c_4 \text{), style (} c_5 \text{)}\}
\]

It is clear that for different decision-makers, the set of decision criteria might vary.
Steps of BWM: Step 2

- Determine the best (e.g. the most important), and the worst (e.g. the least important) criteria.

In this step, the decision-maker identifies the best and the worst criteria. No comparison is made at this stage. For example, for a particular decision-maker, price($c_2$) and style($c_5$) may be the best and the worst criteria respectively.
Steps of BWM: Step 3

- Determine the preference of the best criterion over all the other criteria using a number between 1 and 9 (or other scales). The resulting Best-to-Others (BO) vector would be:

\[ A_B = (a_{B1}, a_{B2}, \ldots, a_{Bn}) \]

where \( a_{Bj} \) indicates the preference of the best criterion \( B \) over criterion \( j \). For our example, the vector shows the preference of \( \text{price}(c_2) \) over all the other criteria.

![Diagram showing the preference of the best criterion over other criteria](image)
Steps of BWM: Step 4

- Determine the preference of all the criteria over the worst criterion using a number between 1 and 9 (or other scales). The resulting Others-to-Worst (OW) vector would be:

\[ A_W = (a_{1W}, a_{2W}, \ldots, a_{nW})^T \]

where \( a_{jW} \) indicates the preference of the criterion \( j \) over the worst criterion \( W \). For our example, the vector shows the preference of all the criteria over style(\( c_5 \)).
Steps of BWM: Step 5

- Find the optimal weights \((w_1^*, w_2^*, \ldots, w_n^*)\)

The optimal weights for the criteria is the one where, for each pair of \(w_B/w_j\) and \(w_j/w_W\), we have \(w_B/w_j = a_{Bj}\) and \(w_j/w_W = a_{jw}\).

To satisfy these conditions for all \(j\), we should find a solution where the maximum absolute differences \(\left|\frac{w_B}{w_j} - a_{Bj}\right|\) and \(\left|\frac{w_j}{w_W} - a_{jw}\right|\) for all \(j\) is minimized.
Steps of BWM: Step 5, min-max

To find the optimal weights, the following optimization model is formulated.

$$\min \max \left\{ \left| \frac{w_B}{w_j} - a_{Bj} \right|, \left| \frac{w_j}{w_W} - a_{jW} \right| \right\}$$

s.t.

$$\sum_j w_j = 1$$

$$w_j \geq 0, \text{ for all } j$$
Steps of BWM: Step 5, Converted *min-max*

Model (1) is converted to the following model.

\[
\begin{align*}
    \text{min } \xi \\
    \text{s.t.} \\
    \left| \frac{w_B}{w_j} - a_{Bj} \right| & \leq \xi, \text{ for all } j \\
    \left| \frac{w_j}{w_W} - a_{jw} \right| & \leq \xi, \text{ for all } j \\
    \sum_{j} w_j = 1 \\
    w_j & \geq 0, \text{ for all } j
\end{align*}
\]

Solving Model(2), the optimal weights \((w_1^*, w_2^*, \ldots, w_n^*)\) are obtained.
Consistency ratio: Definition

**Definition.** A comparison is fully consistent when $a_{Bj} \times a_{jW} = a_{BW}$ for all $j$, where $a_{Bj}$, $a_{jW}$, $a_{BW}$ are respectively the preference of the best criterion over the criterion $j$, the preference of criterion $j$ over the worst criterion, and the preference of the best criterion over the worst criterion.

www.bestworstmethod.com
Consistency ratio: A robust index

As it is likely that we do not have the full consistency, we can calculate the level of consistency using a robust index called consistency ratio:

Consistency ratio (CR) ∈ [0, 1]. The lower the CR the more consistent the comparisons, hence the more reliable results.

<table>

<td>0.4543</td>
<td>0.4599</td>
</tr>
<tr>
<td>9</td>
<td>0.2122</td>
<td>0.3653</td>
<td>0.4055</td>
<td>0.4225</td>
<td>0.4445</td>
<td>0.4587</td>
<td>0.4747</td>
</tr>
</tbody>
</table>

For instance, if we have a problem with 6 criteria and the maximum value in the pairwise comparison system is 7, then the threshold is 0.3931, which implies that values of CR below 0.3931 are acceptable for such a problem.
When we have more than 3 criteria AND a consistency ratio greater than zero, Model (2) has multiple optimal solutions. Solving the following two models the lower bound and the upper bound of the weights are obtained:

\[
\begin{align*}
\text{min } & w_j \\
\text{s.t. } & \left| \frac{w_B}{w_j} - a_{Bj} \right| \leq \xi^*, \text{ for all } j \\
& \left| \frac{w_j}{w_w} - a_{jw} \right| \leq \xi^*, \text{ for all } j \\
& \sum_j w_j = 1 \\
& w_j \geq 0, \text{ for all } j
\end{align*}
\]

(3a)

\[
\begin{align*}
\text{max } & w_j \\
\text{s.t. } & \left| \frac{w_B}{w_j} - a_{Bj} \right| \leq \xi^*, \text{ for all } j \\
& \left| \frac{w_j}{w_w} - a_{jw} \right| \leq \xi^*, \text{ for all } j \\
& \sum_j w_j = 1 \\
& w_j \geq 0, \text{ for all } j
\end{align*}
\]

(3b)

A decision-maker selects an optimal solution from the interval weights. This can be the center of the intervals, for instance.
Linear BWM, *min-max*

We can also minimize the maximum from the set \( \{ \vert w_B - a_{Bj} w_j \vert, \vert w_j - a_{jw} w_w \vert \} \) which results in the following model:

\[
\begin{align*}
\min_j \max \left\{ \vert w_B - a_{Bj} w_j \vert, \vert w_j - a_{jw} w_w \vert \right\} \\
\text{s.t.} \\
\sum_j w_j = 1 \\
w_j \geq 0, \text{ for all } j
\end{align*}
\]
Linear BWM, Converted \textit{min-max}

Model (4) is converted to the following model.

\begin{align*}
\text{min } \xi^L \\
\text{s.t.} \\
\left| w_B - a_{Bj} w_j \right| \leq \xi^L, \text{ for all } j \\
\left| w_j - a_{jw} w_w \right| \leq \xi^L, \text{ for all } j \\
\sum_j w_j = 1 \\
w_j \geq 0, \text{ for all } j
\end{align*}

This is a linear model with a unique solution \((w_1^*, w_2^*, \ldots, w_n^*)\).

\(\xi^L^*\) is considered as a good indicator of the consistency* of the comparisons.

(*note: the \(\xi^L^*\) of Model (5) should not be divided by the consistency index values on page 17)

Model (5) is a good linear \textit{approximation} of Model(2).
An example (buying a car)

For buying a car, a buyer considers five criteria: quality ($c_1$), price ($c_2$), comfort ($c_3$), safety ($c_4$), and style ($c_5$). The buyer provides the following pairwise comparison vectors (BO: Best to Others; OW: Others to Worst).

<table>
<thead>
<tr>
<th>BO</th>
<th>Quality</th>
<th>Price</th>
<th>Comfort</th>
<th>Safety</th>
<th>Style</th>
</tr>
</thead>
<tbody>
<tr>
<td>Best criterion: <strong>Price</strong></td>
<td>2</td>
<td>1</td>
<td>4</td>
<td>3</td>
<td>8</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>OW</th>
<th>Quality</th>
<th>Price</th>
<th>Comfort</th>
<th>Safety</th>
<th>Style</th>
</tr>
</thead>
<tbody>
<tr>
<td>Worst criterion: <strong>Style</strong></td>
<td>4</td>
<td>8</td>
<td>4</td>
<td>2</td>
<td>1</td>
</tr>
</tbody>
</table>

www.bestworstmethod.com
An example (buying a car, Model (2))

Using Model (2) to solve the problem we have:

\[ \bar{\xi}^* = 1 \quad \text{Consistency Ratio} = \frac{\bar{\xi}^*}{\text{Consistency Index}} = \frac{1}{4.47} = 0.22 \]

\[ w_1^* = [0.1579, 0.2469], \quad w_1^*(\text{center}) = 0.2024, \quad w_1^*(\text{width}) = 0.0445 \]
\[ w_2^* = [0.4286, 0.4932], \quad w_2^*(\text{center}) = 0.4609, \quad w_2^*(\text{width}) = 0.0323 \]
\[ w_3^* = [0.1429, 0.1644], \quad w_3^*(\text{center}) = 0.1536, \quad w_3^*(\text{width}) = 0.0108 \]
\[ w_4^* = [0.1111, 0.1579], \quad w_4^*(\text{center}) = 0.1345, \quad w_4^*(\text{width}) = 0.0234 \]
\[ w_5^* = [0.0476, 0.0548], \quad w_5^*(\text{center}) = 0.0512, \quad w_5^*(\text{width}) = 0.0036 \]
An example (buying a car: Model (2))

1. Suppose we have a performance matrix as follows (10-point scale; the higher the better):

   \[
   \begin{align*}
   N & \begin{pmatrix} 8 & 6 & 5 & 8 & 8 \end{pmatrix} \\
   P & \begin{pmatrix} 7 & 9 & 6 & 7 & 7 \end{pmatrix} \\
   H & \begin{pmatrix} 8 & 4 & 7 & 6 & 6 \end{pmatrix}
   \end{align*}
   \]

2. And here are the weights we get from page 22 (center of the intervals):

   \[w^* = \{0.2024, 0.4609, 0.1536, 0.1345, 0.0512\}\]

3. Then we can get the overall value of each car using the following function:

   \[V_i = \sum_{j=1}^{n} w_j p_{ij}\]

If the alternative scores (performance matrix) are of different scales (ton, euro, km) we first normalize the scores:

   \[x_k^{\text{norm}} = \begin{cases} 
   \frac{x_k}{\max\{x_i\}}, & \text{if } x \text{ is positive (such as quality),} \\
   1 - \frac{x_k}{\max\{x_i\}}, & \text{if } x \text{ is negative (such as price).} 
\end{cases}\]

- \[V_N = (8 \times 0.2024) + (6 \times 0.4609) + (5 \times 0.1536) + (8 \times 0.1345) + (8 \times 0.0512) = 6.6382\]
- \[V_R = (7 \times 0.2024) + (9 \times 0.4609) + (6 \times 0.1536) + (7 \times 0.1345) + (7 \times 0.0512) = 7.7864\]
- \[V_H = (8 \times 0.2024) + (4 \times 0.4609) + (7 \times 0.1536) + (6 \times 0.1345) + (6 \times 0.0512) = 5.6522\]

This car, with the highest overall score, is selected.

www.bestworstmethod.com
An example (buying a car: Model (5))

If we solve the problem using the Linear BWM (Model (5)) we get the following weights:

\[ w^* = \{0.246, 0.431, 0.154, 0.123, 0.046\} \]

With the following consistency ratio:

\[ \xi^* \approx 0.061 \]

As can be seen the weights are slightly different from the center of intervals, yet we come to the same best decision.

\[ V_N = (8 \times 0.246) + (6 \times 0.431) + (5 \times 0.154) + (8 \times 0.123) + (8 \times 0.046) = 6.676 \]

Again, this car, with the highest overall score, is selected.

\[ V_R = (7 \times 0.246) + (9 \times 0.431) + (6 \times 0.154) + (7 \times 0.123) + (7 \times 0.046) = 7.708 \]

\[ V_H = (8 \times 0.246) + (4 \times 0.431) + (7 \times 0.154) + (6 \times 0.123) + (6 \times 0.046) = 5.784 \]
Bayesian BWM (A group decision-making model)

\[
P(w^{agg}, w^{1:K} \mid A_B^{1:K}, A_W^{1:K}) \propto P(A_B^{1:K}, A_W^{1:K} \mid w^{agg}, w^{1:K}) P(w^{agg}, w^{1:K})
\]

\[
= P(w^{agg}) \prod_{k=1}^{K} P(A_W^k \mid w^k) P(A_B^k \mid w^k) P(w^k \mid w^{agg}).
\]

\[
P(x) = \sum_y P(x, y)
\]

\[
P(A_W^k \mid w^{agg}, w^k) = P(A_W^k \mid w^k)
\]

\[
A_B^k \mid w^k \sim \text{multinomial}(1/w^k)
\]

\[
A_W^k \mid w^k \sim \text{multinomial}(w^k)
\]

\[
w^k \mid w^{agg} \sim \text{Dir}(\gamma \times w^{agg})
\]

\[
\gamma \sim \text{gamma}(a, b)
\]

\[
w^{agg} \sim \text{Dir}(\alpha)
\]

www.bestworstmethod.com
Bayesian BWM (A group decision-making model): Credal Ranking

\[ P(c_i > c_j) = \int I_{(w_i^{agg} > w_j^{agg})} P(w^{agg}) \]

\[ P(c_i > c_j) = \frac{1}{Q} \sum_{q=1}^{Q} I(w_i^{agg_q} > w_j^{agg_q}) \]

\[ P(c_j > c_i) = \frac{1}{Q} \sum_{q=1}^{Q} I(w_j^{agg_q} > w_i^{agg_q}) \]

Salient features: Data efficiency

![Graph showing number of pairwise comparisons for AHP and BWM methods.](https://www.bestworstmethod.com)
Salient features: Structured pairwise comparison

- BWM makes the comparisons in a **structured way**, which makes the judgment easier and more understandable, and more importantly leads to **more consistent comparisons**, hence more reliable weights/rankings.

In our daily life we usually compare things to some reference points!

BWM is as simple as possible. But not simpler!

[www.bestworstmethod.com](http://www.bestworstmethod.com)
Salient features: Debiasing Strategy

- It has the debiasing strategy “consider-the-opposite”

Condition 1: $1 \times 2 \times 3 \times 4 \times 5 \times 6 \times 7 \times 8$
- Mean answer: ?

Condition 2: $8 \times 7 \times 6 \times 5 \times 4 \times 3 \times 2 \times 1$
- Mean answer: ?

Anchoring and adjustment

www.bestworstmethod.com
Salient features: Compromise/Consensus

Weight of alternatives

Expert 1; Expert 2; Expert 3
Highlights

• BWM is an easy-to-understand and easy-to-apply method.
• BWM makes the comparisons in a structured way.
• BWM leads to more consistent comparisons, hence more reliable weights/rankings.
• BWM is suitable for both situations: flexibility is desirable (non-linear BWM); flexibility is not desirable (linear BWM).
• BWM can supports a single decision-maker.
• BWM is also proper for group decision-making.
• BWM supports reaching consensus in a natural way.
• BWM is efficient in terms of input data.
• BWM can be applied to different MCDM problems with qualitative and quantitative criteria.
• BWM is compatible with many other existing MCDM methods.
